1 The Hamiltonian

We consider a Hamiltonian acting on n qubits:

$$H = \alpha(s_1 \otimes s_2 \otimes \dots \otimes s_n) \tag{1}$$

where s_i are Pauli matrices (X, Y, Z), and α is a scalar. Our goal is to implement the time evolution operator efficiently:

$$e^{-itH} = e^{-it\alpha(s_1 \otimes s_2 \otimes \dots \otimes s_n)}. (2)$$

2 The Challenge

- H is a $2^n \times 2^n$ matrix, making direct exponentiation impractical.
- Quantum circuits use polynomially many gates (O(poly(n))), so we need an efficient approach.

3 Unitary Transformation Trick

We use the key identity:

$$Ue^{-i\alpha H}U^{\dagger} = e^{-i\alpha UHU^{\dagger}}. (3)$$

This follows from the definition of the matrix exponential.

Proof. Expanding the power series:

$$e^{-i\alpha H} = \sum_{k=0}^{\infty} \frac{(-i\alpha H)^k}{k!},\tag{4}$$

and applying conjugation by U:

$$Ue^{-i\alpha H}U^{\dagger} = U\left(\sum_{k=0}^{\infty} \frac{(-i\alpha H)^k}{k!}\right)U^{\dagger}.$$
 (5)

Using $UHU^{\dagger} = H'$, we get:

$$Ue^{-i\alpha H}U^{\dagger} = \sum_{k=0}^{\infty} \frac{(-i\alpha UHU^{\dagger})^k}{k!} = e^{-i\alpha H'}.$$
 (6)

4 Diagonalizing H

Each Pauli matrix s_i can be diagonalized by a single-qubit unitary U_i :

5 Diagonalization of Pauli Terms

6 Single-Qubit Pauli Matrix Diagonalization

7 Pauli Matrices

The Pauli matrices are fundamental operators in quantum mechanics:

$$X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad Z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$
 (7)

• Pauli-X diagonalization:

$$HXH = Z \tag{8}$$

The Hadamard gate H transforms X to diagonal Z form.

• Pauli-Y diagonalization:

$$U_Y Y U_Y^{\dagger} = Z$$
 where $U_Y = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1\\ i & -i \end{pmatrix}$ (9)

The unitary U_Y transforms Y to diagonal Z form.

1

Applying these transformations to all qubits, we rewrite the evolution operator as:

$$e^{-itH} = (U_1 \otimes \cdots \otimes U_n)e^{-i\alpha t(z_1 \otimes \cdots \otimes z_n)}(U_1^{\dagger} \otimes \cdots \otimes U_n^{\dagger}), \tag{10}$$

where z_i are now either I or Z, making the Hamiltonian diagonal.

8 Why This Helps

By diagonalizing H, we reduce the problem to implementing:

$$e^{-i\alpha t Z \otimes Z \otimes \cdots \otimes Z},$$
 (11)

which is simple because:

- \bullet Pauli Z matrices are diagonal, making exponentiation trivial, example of diagonalization.
- The circuit needs only controlled phase gates, requiring O(n) quantum gates.

9 Conclusion

Using unitary transformations, we efficiently simulate the time evolution of a tensor-product Pauli Hamiltonian in polynomial time, making it feasible for quantum computation.
